**TITLE: IMPROVED, LENGTH-ADJUSTABLE TOPSTAY FOR RIGGERS**

**BACKGROUND OF THE INVENTION**

1. Field of the Invention:

The present invention relates to riggers for rowing and sculling boats and, more specifically, to topstays used with riggers.

2. Description of the Related Art:

Narrow rowing and sculling boats such as racing shells, are typically equipped with laterally extending riggers used to support oarlocks outboard of the boat hull. Riggers transfer the principle load from the oarlock pin to the boat hull structure. The oarlock pin is fixed rigidly to the rigger, seats the oarlock, and extends generally upward and vertically from the rigger. The load introduced during a rowing stroke causes the rigger and the oarlock pin to deflect. Topstays, which attach typically by means of bolts and nuts at their outer end to the top of the oarlock pin and at their inner end to the boat hull, are commonly used to reduce such undesirable deflection.

1       The oarlock pins generally can be moved in the lateral direction of the boat to vary the  
2       rower's leverage on the oar. In some cases, the oarlock pin can be moved in the longitudinal  
3       direction of the boat to change a rower's position front and aft, relative to the oarlock pin. It  
4       is also common for oarlock pins to be tilted in the longitudinal direction of the boat and also  
5       in the lateral direction of the boat, to set the desired pitch angles for the oar blade as it moves  
6       through the water. Because the rigger is a rigid structure and because the position of the  
7       oarlock may be adjusted in the manner described, it becomes essential that the topstays,  
8       which attach at their outer end to the top of the oarlock pin and attach at their inner end to the  
9       boat hull, be adjustable to accommodate the new position of the top end of the oarlock pin  
10      relative to the topstay attachment point at the boat hull.

11       Typically, length-adjustable topstays comprise two tubular members which telescope  
12      and are secured with clamps or which are connected with a turnbuckle. In most cases, the  
13      outer tubular member connected to the top of the oarlock pin can be rotated around its  
14      longitudinal axis relative to the inner tubular member which attaches to the boat hull and thus  
15      provides some additional but limited adjustability. Typically, the inner and outer attachment  
16      point surfaces of the topstay are created by flattening the corresponding tube ends and by  
17      shaping and bending the flattened tube ends to match the mating surfaces at the top end of the  
18      oarlock pin and on the boat hull. The manufacturing method to create the flattened tube ends  
19      on the topstay is inherently inaccurate and yields topstays which, in the best-case, fit the  
20      mating surfaces at the top end of the oarlock pin and the boat hull only for one specific  
21      position of the oarlock pin. When the oarlock pin is moved into a position other than this  
22      best-case position, the attachment surfaces of the topstay do not match the mating surfaces at  
23      the top of the oarlock pin and at the boat hull. When the bolts and nuts are used to attach the

1 topstay to the oarlock pin and the boat hull, unwanted stresses are introduced. These  
2 unwanted stresses can damage of the boat hull at the attachment point for the topstay.  
3 Further, depending on the boat hull construction, such unwanted stresses can bend and deflect  
4 the boat hull and thus cause greater damage and form cracks in the boat hull. In addition,  
5 such unwanted stresses bend and deflect the oarlock pin and the rigger, thus changing the  
6 desired settings for the oar pitch and increasing the danger of snapping off an oarlock pin.

7         Conventional topstays have various mechanisms to adjust their lengths which  
8 generally fall into two categories. Topstays with a length adjusting mechanism of the first  
9 category have one tubular member of the topstay sliding into a larger diameter tubular  
10 member of the topstay which has at least two axial cuts at its end so that it can be tightened  
11 onto the inner tubular member by means of hose clamps. This simple mechanism relies on  
12 friction and there is no guarantee that any length position is positively secured. To overcome  
13 this drawback, circumferential grooves are formed on the outer surface of the smaller  
14 diameter tubular member for the outer tubular member to bite into when tightened. While  
15 this provides a secure length adjustment, the length adjustment is now incremental and not  
16 continuous. Topstays with a length adjusting mechanism of the second category have a  
17 threaded connection between the two tubular members with the smaller diameter tubular  
18 member threading into the larger diameter tubular member. While this provides a simple and  
19 secure length adjusting mechanism, the length adjustment can only be done incrementally,  
20 one full 360-degree turn at a time. The size of the increment corresponds to the pitch chosen  
21 for the thread. To keep the secure length adjustment of a threaded connection but to gain  
22 continuous adjustability, it is common to unite the two tubular members of the topstay with a  
23 somewhat unwieldy and heavier turnbuckle arrangement.

1 With their outer attachment point surfaces created by flattening and bending the outer  
2 ends of its tubular telescoping members, conventional topstays are typically asymmetric with  
3 respect to the side they attach to on the row or sculling boat hull. With port and starboard  
4 topstays not interchangeable, additional spare parts are necessary in case a topstay must be  
5 replaced.

6 The present invention substantially departs from the conventional concepts and  
7 designs of the prior art, and in so doing provides a topstay for rowing or sculling boat riggers  
8 adjustable in such a way that the surfaces of its outer end and its inner end always match the  
9 respective mating surface at the top end of the oarlock pin and at the boat hull, thus  
10 eliminating unwanted stresses and the related deformation and damage to the boat hull and  
11 the related deformation of the oarlock pin and of the rigger.

## 12 SUMMARY OF THE INVENTION

13 It is an object of the present invention to provide an improved, length adjustable  
14 topstay for a rigger.

15 It is another object of the invention to provide such a topstay that can be used on the  
16 port or starboard side of the hull.

17 It is a further object of the present invention to provide such a topstay that does not  
18 create excessive stress on the hull and the oarlock pin when the oarlocks are moved in  
19 different locations on the riggers.

20 These and other objects are met by the topstay presented herein that comprises an  
21 outer and inner tube member, longitudinally aligned and telescopically connected together.  
22 Formed on the distal end of the outer tube member is a transversely aligned tubular housing  
23

that receives connects to a pin connector. In the preferred embodiment, the tubular housing is aligned approximately 45 degrees to the longitudinal axis of the outer tubular member.

During assembly, the pin connector is selectively rotated and then fixed inside the tubular housing. The pin connector is then connected to the oarlock pin.

Inserted into the proximal end of the inner tubular member is a cylindrical plug. Perpendicularly aligned and attached to the cylindrical plug is a pivot connector. During assembly, the base bracket is securely attached to the boat hull. The pivot connector is transversely aligned over the base bracket and suspended between two bores formed on the base bracket. The topstay is then pivoted over the base bracket and axially rotated so that the pin connector may be properly aligned on the oarlock pin.

Before explaining at least one preferred embodiment of the invention in detail, it is to be understood that the invention is not limited in its application to the details of construction and to the arrangements of the individual components set forth in the following description or illustrated in the drawings. The invention is capable of other embodiments and of being practiced and carried out in various ways. In particular, an embodiment comprising a conventional topstay and only one additional joint at its inner end as described for this invention, will have marked advantages over a state of the art topstay by eliminating most undesirable stresses exerted onto the boat hull by a conventional topstay without aforesaid joint and thus in effect eliminating most stress induced damages to the boat hull.

## DESCRIPTION OF THE DRAWINGS

Fig. 1 is a side elevational view of the row or sculling boat rigger with one embodiment of a topstay installed.

1 Fig. 2 is a top plan view of the row or sculling boat rigger shown in Fig. 1.

2 Fig. 3 is an exploded perspective view of one embodiment of a topstay shown in Figs.  
3 1 and 2.

4 Fig. 4 is a cross section view of the outer end of one embodiment of a topstay.

5 Fig. 5 is an exploded perspective view of a second embodiment of the outer end of the  
6 topstay.

7 Fig. 6 is a cross section view of the outer end of the second embodiment of the  
8 topstay shown in Fig. 5.

9  
10 **DESCRIPTION OF THE PREFERRED EMBODIMENT(S)**

11 Referring to the drawings, and particularly to Figs. 1 and 2, a topstay 11 according to  
12 the present invention is secured at its distal end by a bolt 12, to the top end of the oarlock pin  
13 13 and is secured at its distal end by bolt 14 to the indicated boat hull 15. The bottom of the  
14 oarlock pin 13 is depicted as being secured by a nut 16 to the rigger 17 attached to the boat  
15 hull. An oarlock 18 is shown in phantom lines for clarity.

16 As shown in Fig. 3, the topstay 11 comprises an outer tubular member 20 of metal,  
17 preferably aluminum. Attached via a weld 28 to the distal end 21 of the tubular member 20 is  
18 a short tubular housing 24, made of metal, preferably aluminum. The longitudinal axis 25 of  
19 the tubular housing 24 intersects the longitudinal axis 23 of the outer tubular member 20 at  
20 an angle other than zero, preferably at or near 45 degrees.

21 Inserted into the opposite ends 26, 27 of the tubular housing 24 are two identical  
22 plugs 30 and 32. Plugs 30, 32 are made of lightweight material, preferably a plastic such as  
23 nylon and act as seats for the pin connector 35 and bolt 40. The pin connector 35 includes a

1 flat end surface 36 formed on one end and a cylindrical neck 38 found on the opposite end. A  
2 hole 37 is drilled in the flat end surface 36 of the pin connector 35 which receives a bolt 12  
3 for securing it to the top end of the oarlock pin 13. Formed longitudinally inside the  
4 cylindrical neck 38 is a threaded bore 39 that connects to bolt 40 when longitudinally aligned  
5 and extended into the central passageway formed inside the tubular housing 24. A lock  
6 washer 41 may be disposed over the bolt 40 to prevent the bolt 40 from loosening. A flat  
7 washer 42 is also added to protect the plug 32 from being marred by the lock washer 41.

8 The pin connector 35, the tubular housing 24 and bolt 40 comprise a first joint on the  
9 topstay 11. Referring to Fig. 4, by loosening bolt 40, the pin connector 35 can be rotated  
10 around its longitudinal axis and when the correct setting has been achieved, tightening the  
11 bolt 40 fixes the position of pin connector 35 inside the tubular housing 24.

12 Inserted and fixed in position in the proximal end 22 of the outer tubular member 20  
13 is a sleeve 45. The sleeve 45 includes a longitudinally aligned threaded bore 46 that  
14 selectively connects to the external threads 60 on the inner tubular member 50. The sleeve 45  
15 is made of nylon or other suitable material capable of being bonded or welded to the outer  
16 tubular member 20.

17 The inner tubular member 50 has a external threads 60 formed near its distal end 51  
18 that connect to threaded bore 46 formed on the sleeve 45. The inner tubular member 50 is  
19 made of metal preferably aluminum and the length of its external threads is determined by the  
20 desired range over which the length of the topstay 11 can be adjusted. A jam nut 54 is  
21 attached to the threads 60 and enables the user to lock the inner tubular member 50 in a  
22 desired length of the outer tubular member 20.

23 Inserted into the proximal end 52 of the inner tubular member 50 is a plug 56. The

1 plug 56 includes a wide flange surface 57 that extends over the proximal end 52. Formed  
2 inside the plug 56 is a threaded bore 58. The plug 56 is secured to the inner tubular member  
3 50 by either bonding or welding, depending on the material choice and preference.

4 Aligned transversely over the flange surface 57 of the plug 56 is a cylindrical pivot  
5 connector 65. Extending transversely through the center axis of the pivot connector 65 is a  
6 non-threaded bore 66. The bore 66 is countersunk at its opposite ends to improved seating  
7 for the plug 56 and for a spring washer 55 as shown in Fig. 3. During assembly, a bolt 70  
8 extends through the pivot connector 65 and connects to the threaded bore 58 formed on the  
9 plug 56. An optional spring washer 68 may be placed around the bolt 70. The bolt 70 is then  
10 tightened to securely attach the pivot connector 65 to the proximal end 52 of the inner tubular  
11 member 50.

12 Also shown in Fig. 3, the proximal end 52 of the inner tubular member 50 is  
13 connected to a base bracket 75. The base bracket 75 includes a flat plate 76 with two upward  
14 extending arms 78, 80. A main hole 77 is formed on the flat plate 76 that receives a bolt 14  
15 to attach the base bracket 75 to the boat hull. Formed on the arms 78, 80 are holes 79, 81,  
16 respectively, designed to receive and hold the pivot connector 65 transversely over the base  
17 bracket 75. During assembly, the pivot connector 65 is extended between the two holes 79,  
18 81 to attached the distal end of the topstay to the base bracket 56.

19 It should be understood that the plug 56, pivot connector 65, and base bracket 75  
20 make a second joint formed on the topstay 11 that allows the user to diagonally align the  
21 topstay over the base bracket 75.

22 With proper modifications known to one skilled in the art at least a portion of the  
23 outer tubular member 20 and the inner tubular member 50, can be of composite material such

1 as polymeric resin reinforced with fibers.

2 During assembly, the overall length of the topstay 11 must be precisely adjusted. This  
3 is achieved by providing a means for continuous adjustment of the length with a single thread  
4 joint between the outer tubular member 20 and the inner tubular member 50. The bolt 70 is  
5 sufficiently tightened only to the point at which the inner tubular member 50 can still be  
6 rotated by hand over the base bracket 75. The spring washer 68 ensures a tight joint and bolt  
7 70 can comprise a nylon patch preventing it from loosening.

8 To properly align the pin connector 35 on the oarlock pin 13, the bolts 14, 40 and jam  
9 nut 54 are loosened. While supporting the tubular housing 24, the inner tubular member 50  
10 is manually rotated until the hole 37 of the pin connector 35 is aligned with the hole (not  
11 shown) in the top of the oarlock pin 13. Bolt 12 is then inserted into the hole 37 and finger-  
12 tightened. Bolt 14 is then tightened completely. At this point it might be necessary to make  
13 further slight adjustments to the length by turning the inner tubular member 50 before  
14 tightening bolt 12, then bolt 40 and jam nut 54.

15 A second embodiment for the first joint is depicted in Figs. 5 and Fig. 6 which shows  
16 the pin connector 35 seated directly in the modified outer tubular member 61. The two  
17 suitably identical spacers 82 and 82' are diagonally cut and contoured on one side to fit the  
18 outer diameter of the outer tubular member 61 so that the pin connector 35 is diagonally  
19 aligned at approximately 45 degrees with respect to the modified outer tubular member 80.  
20 The opposite surfaces of the spacers 82, 82' are squared off to properly support pin connector  
21 35 and bolt 40 with its lock washer 41 and its washer 42. The modified outer tubular member  
22 61 includes an end opening 83 in which an end plug 85 is inserted. Formed on the end plug  
23 85 is a transversely aligned bore 86. The end plug 85 is contoured to close the outer tubular

1 member 61 and to provide stiffness to this outer joint and to the cross section of the modified  
2 outer tubular member 61 when bolt 40 is tightened. Formed on the distal end of the modified  
3 tubular member 61 are two holes 72, 73 that enable the plug connector 35 and bolt 40 to  
4 extend through and connect together. The adjustments for pin connector 35 are done  
5 identically as described for the first embodiment described above and as shown in Fig. 3 and  
6 Fig. 4.

7         It should be understood that the topstay 11 could include only the plug connector 35  
8 that connects to the outer tubular members 20 and 61. the topstay 11 could also include a  
9 fixed plug connector as used in the prior art and the plug 56, pivot connector 65, and base  
10 bracket 75 as described herein. In the preferred embodiment, however, the top stay 11  
11 includes both joints along with the telescoping adjustment feature.

12         In compliance with the statute, the invention described herein has been described in  
13 language more or less specific as to structural features. It should be understood, however,  
14 that the invention is not limited to the specific features shown, since the means and  
15 construction shown is comprised only of the preferred embodiments for putting the invention  
16 into effect. The invention is therefore claimed in any of its forms or modifications within the  
17 legitimate and valid scope of the amended claims, appropriately interpreted in accordance  
18 with the doctrine of equivalents.  
19
